

How to Install LEMP Stack on Ubuntu 22.04 Server/Desktop

📅 Last Updated: September 15th, 2022 👤 Xiao Guoan (Admin) 💬 22
Comments 🏠 Ubuntu

This tutorial is going to show you how to install **LEMP stack** (Nginx, MariaDB, and PHP8.1) on **Ubuntu 22.04**. A software stack is a set of software tools bundled together. LEMP stands for Linux, Nginx (Engine-X), MariaDB/MySQL, and PHP, all of which are open source and free to use.

It is the most common software stack that powers dynamic websites and web applications.

- Linux is the operating system.
- Nginx is the web server.
- MariaDB/MySQL is the database server.
- PHP is the server-side scripting language responsible for generating dynamic web pages.

Requirements

To follow this tutorial, you need an Ubuntu 22.04 OS running on your local computer or on a remote server.

If you are looking for a virtual private server (VPS), I recommend [Kamatera VPS](#), which features:

- 30 days free trial.
- Starts at \$4/month (1GB RAM)
- High-performance KVM-based VPS

- 9 data centers around the world, including United States, Canada, UK, Germany, The Netherlands, Hong Kong, and Isreal.

Follow the tutorial linked below to create your Linux VPS server at Kamatera.

- [How to Create a Linux VPS Server on Kamatera](#)

Once you have a VPS running Ubuntu 22.04, follow the instructions below.

And if you need to set up LEMP stack with a domain name, I recommend buying domain names from [NameCheap](#) because the price is low and they give whois privacy protection free for life.

Step 1: Update Software Packages

Before we install the LEMP stack, it's a good practice to update the repository and software packages by running the following commands on your Ubuntu 22.04 OS.

```
sudo apt update  
  
sudo apt upgrade -y
```

Step 2: Install Nginx Web Server

Nginx is a high-performance web server and is very popular these days. It also can be used as a [reverse proxy](#) and caching server. Enter the following command to install Nginx Web server.

```
sudo apt install nginx
```

After it's installed, we can enable Nginx to auto-start at boot time by running the following command.

```
sudo systemctl enable nginx
```

Then start Nginx with this command:

```
sudo systemctl start nginx
```

Now check out its status.

```
sudo systemctl status nginx
```

Output:

```
● nginx.service - A high performance web server and a reverse proxy server
   Loaded: loaded (/lib/systemd/system/nginx.service; enabled; vendor preset: enabled)
   Active: active (running) since Fri 2022-04-10 14:11:43 UTC; 3s ago
     Docs: man:nginx(8)
   Process: 8533 ExecStartPre=/usr/sbin/nginx -t -q -g daemon on; master_process on; (code=exited, status=0/SUCCESS)
   Process: 8545 ExecStart=/usr/sbin/nginx -g daemon on; master_process on; (code=exited, status=0/SUCCESS)
   Main PID: 8549 (nginx)
     Tasks: 3 (limit: 9451)
    Memory: 3.9M
   CGroup: /system.slice/nginx.service
```

```
└─8549 nginx: master proc  
ess /usr/sbin/nginx -g daemon on; mast  
er_process on;  
└─8550 nginx: worker proc  
ess  
└─8551 nginx: worker proc  
ess
```

“**Enabled**” indicates that auto-start at boot time is enabled and we can see that Nginx is running. You can also see how much RAM Nginx is using from the output. If the above command doesn’t immediately quit after running. You need to press “q” to make it quit.

Check Nginx version.

```
nginx -v
```

Output:

```
nginx version: nginx/1.18.0 (Ubuntu)
```

Now type in the public IP address of your Ubuntu 22.04 server in the browser address bar. You should see the “Welcome to Nginx” Web page, which means Nginx Web server is running properly. If you are installing LEMP on your local Ubuntu 22.04 computer, then type 127.0.0.1 or localhost in the browser address bar.

Welcome to nginx!

If you see this page, the nginx web server is successfully installed and working. Further configuration is required.

For online documentation and support please refer to nginx.org.
Commercial support is available at nginx.com.

Thank you for using nginx.

If the connection is refused or failed to complete, there might be a firewall preventing incoming requests to TCP port 80. If you are using iptables firewall, then you need to run the following command to open TCP port 80.

```
sudo iptables -I INPUT -p tcp --dport  
80 -j ACCEPT
```

If you are using [the UFW firewall](#), then run this command to open TCP port 80.

```
sudo ufw allow http
```

Finally, we need to make www-data (Nginx user) as the owner of web directory. By default, it's owned by the root user.

```
sudo chown www-data:www-data /usr/share  
nginx/html -R
```

Step 3: Install MariaDB Database

Server

MariaDB is a drop-in replacement for MySQL. It is developed by former members of MySQL team who are concerned that Oracle might turn MySQL into a closed-source product. Enter the following command to install MariaDB on Ubuntu 22.04.

```
sudo apt install mariadb-server mariad  
b-client
```

After it's installed, MariaDB server should be automatically started. Use **systemctl** to check its status.

```
systemctl status mariadb
```

Output:

```
● mariadb.service - MariaDB 10.6.7 database server
   Loaded: loaded (/lib/systemd/system/mariadb.service; enabled; vendor preset: enabled)
   Active: active (running) since Fri 2022-04-10 14:19:16 UTC; 18s ago
     Docs: man:mysql(8)
           https://mariadb.com/kb/en/library/systemd/
   Main PID: 9161 (mysqld)
   Status: "Taking your SQL requests now..."
     Tasks: 31 (limit: 9451)
    Memory: 64.7M
    CGroup: /system.slice/mariadb.service
           └─9161 /usr/sbin/mysqld
```

Hint: If the above command doesn't immediately quit after running. You need to press "q" to make it quit.

If it's not running, start it with this command:

```
sudo systemctl start mariadb
```

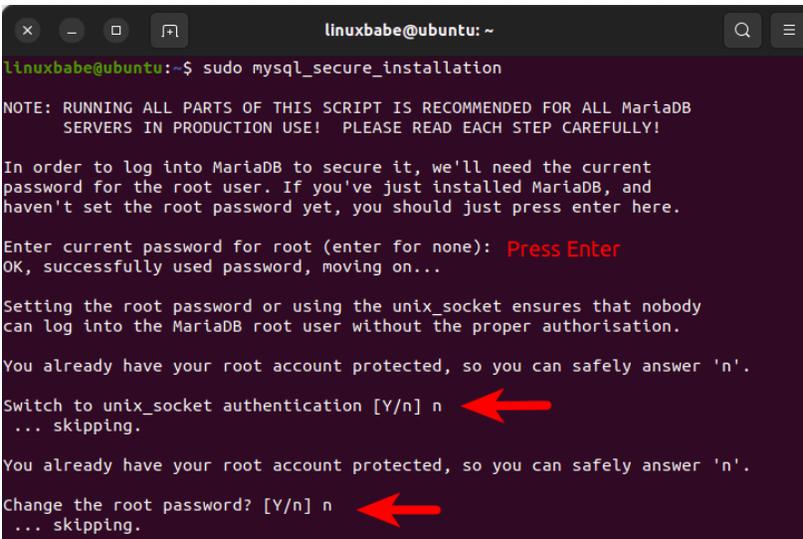

To enable MariaDB to automatically start at boot time, run

```
sudo systemctl enable mariadb
```

Now run the post-installation security script.

```
sudo mysql_secure_installation
```

- When it asks you to enter MariaDB root password, press Enter key as the root password isn't set yet.
- Don't switch to unix_socket authentication because MariaDB is already using unix_socket authentication.
- Don't change the root password, because you don't need to set root password when using unix_socket authentication.

```
linuxbabe@ubuntu: ~  
linuxbabe@ubuntu:~$ sudo mysql_secure_installation  
NOTE: RUNNING ALL PARTS OF THIS SCRIPT IS RECOMMENDED FOR ALL MariaDB  
SERVERS IN PRODUCTION USE! PLEASE READ EACH STEP CAREFULLY!  
  
In order to log into MariaDB to secure it, we'll need the current  
password for the root user. If you've just installed MariaDB, and  
haven't set the root password yet, you should just press enter here.  
Enter current password for root (enter for none): Press Enter  
OK, successfully used password, moving on...  
  
Setting the root password or using the unix_socket ensures that nobody  
can log into the MariaDB root user without the proper authorisation.  
  
You already have your root account protected, so you can safely answer 'n'.  
Switch to unix_socket authentication [Y/n] n  
... skipping.  
  
You already have your root account protected, so you can safely answer 'n'.  
Change the root password? [Y/n] n  
... skipping.
```

Next, you can press Enter to answer all remaining questions, which will remove anonymous user, disable remote root login and remove test database. This step is a basic requirement for MariaDB database security. (Notice that Y is capitalized, which means it is the default answer.)

```
By default, a MariaDB installation has an anonymous user, allowing anyone
to log into MariaDB without having to have a user account created for
them. This is intended only for testing, and to make the installation
go a bit smoother. You should remove them before moving into a
production environment.

Remove anonymous users? [Y/n] Press Enter
... Success!

Normally, root should only be allowed to connect from 'localhost'. This
ensures that someone cannot guess at the root password from the network.

Disallow root login remotely? [Y/n] Press Enter
... Success!

By default, MariaDB comes with a database named 'test' that anyone can
access. This is also intended only for testing, and should be removed
before moving into a production environment.

Remove test database and access to it? [Y/n] Press Enter
- Dropping test database...
... Success!
- Removing privileges on test database...
... Success!

Reloading the privilege tables will ensure that all changes made so far
will take effect immediately.

Reload privilege tables now? [Y/n] Press Enter
... Success!

Cleaning up...

All done! If you've completed all of the above steps, your MariaDB
installation should now be secure.

Thanks for using MariaDB!
```

By default, the MariaDB package on Ubuntu uses `unix_socket` to authenticate user login, which basically means you can use username and password of the OS to log into MariaDB console. So you can run the following command to log in without providing MariaDB root password.

```
sudo mariadb -u root
```

To exit, run

```
exit;
```

Check MariaDB server version information.

```
mariadb --version
```

As you can see, we have installed MariaDB 10.6.7.

```
mariadb Ver 15.1 Distrib 10.6.7-MariaD
B, for debian-linux-gnu (x86_64) using
```

Step 4: Install PHP8.1

PHP8.1 is included in Ubuntu 22.04 repository and has a minor performance improvement over PHP8.0. Enter the following command to install PHP8.1 and some common extensions.

```
sudo apt install php8.1 php8.1-fpm php8.1-mysql php-common php8.1-cli php8.1-common php8.1-opcache php8.1-readline php8.1-mbstring php8.1-xml php8.1-gd php8.1-curl
```

PHP extensions are commonly needed for content management systems (CMS) like [WordPress](#). For example, if your installation lacks `php8.1-xml`, then some of your WordPress site pages may be blank and you can find an error in Nginx error log like:

```
PHP message: PHP Fatal error: Uncaught Error: Call to undefined function xml_parser_create()
```

Installing these PHP extensions ensures that your CMS runs smoothly. Now start `php8.1-fpm`.

```
sudo systemctl start php8.1-fpm
```

Enable auto-start at boot time.

```
sudo systemctl enable php8.1-fpm
```

Check status:

```
systemctl status php8.1-fpm
```

Sample output:

```
● php8.1-fpm.service - The PHP 8.1 FastCGI Process Manager
   Loaded: loaded (/lib/systemd/system/php8.1-fpm.service; enabled; vendor
pr>
   Active: active (running) since Fri 2022-04-10 14:40:26 UTC; 12s ago
     Docs: man:php-fpm8.1(8)
   Process: 21019 ExecStartPost=/usr/lib/php/php-fpm-socket-helper install
/ru>
   Main PID: 21012 (php-fpm8.1)
   Status: "Processes active: 0, idle: 2, Requests: 0, slow: 0, Traffic: 0
req>
     Tasks: 3 (limit: 9451)
    Memory: 9.4M
    CGroup: /system.slice/php8.1-fpm.service
           └─21012 php-fpm: master process (/etc/php/8.1/fpm/php-fpm.conf)
           └─21017 php-fpm: pool www
           └─21018 php-fpm: pool www
```

If the above command doesn't immediately quit after running. You need to press "q" to make it quit.

Step 5: Create an Nginx Server Block

An Nginx server block is like a virtual host in Apache. We will not use the default server block because it's inadequate to run

PHP code and if we modify it, it becomes a mess. So remove the default symlink in sites-enabled directory by running the following command. (It's still available as /etc/nginx/sites-available/default.)

```
sudo rm /etc/nginx/sites-enabled/default
```

Then use a command-line text editor like Nano to create a new server block file under **/etc/nginx/conf.d/** directory.

```
sudo nano /etc/nginx/conf.d/default.conf
```

Paste the following text into the file. The following snippet will make Nginx listen on IPv4 port 80 and IPv6 port 80 with a catch-all server name.

```
server {
    listen 80;
    listen [::]:80;
    server_name _;
    root /usr/share/nginx/html/;
    index index.php index.html index.htm
    index.nginx-debian.html;

    location / {
        try_files $uri $uri/ /index.php;
    }

    location ~ \.php$ {
        fastcgi_pass unix:/run/php/php8.1-
        fpm.sock;
        fastcgi_param SCRIPT_FILENAME $doc
        ument_root$fastcgi_script_name;
```

```
    include fastcgi_params;
    include snippets/fastcgi-php.conf;
}

# A long browser cache lifetime can speed up repeat visits to your page
location ~* \.(jpg|jpeg|gif|png|webp|svg|woff|woff2|ttf|css|js|ico|xml)$ {
    access_log      off;
    log_not_found   off;
    expires         360d;
}

# disable access to hidden files
location ~ /\.ht {
    access_log off;
    log_not_found off;
    deny all;
}
}
```

Save and close the file. (To save a file in Nano text editor, press `Ctrl+O`, then press `Enter` to confirm. To exit, press `Ctrl+X`.)

Then test Nginx configurations.

```
sudo nginx -t
```

If the test is successful, reload Nginx.

```
sudo systemctl reload nginx
```

Step 6: Test PHP

To test PHP-FPM with Nginx Web server, we need to create a `info.php` file in the webroot directory.

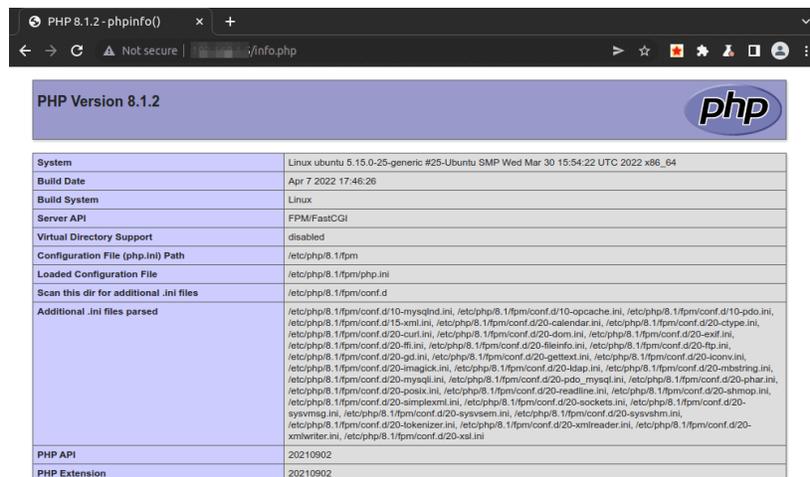

```
sudo nano /usr/share/nginx/html/info.php
```

Paste the following PHP code into the file.

```
<?php phpinfo(); ?>
```

Save and close the file. Now in the browser address bar, enter `server-ip-address/info.php`. Replace `server-ip-address` with your actual IP. If you follow this tutorial on your local computer, then type `127.0.0.1/info.php` or `localhost/info.php`.

You should see your server's PHP information. This means PHP scripts can run properly with Nginx web server.

PHP Version 8.1.2	
System	Linux ubuntu 5.15.0-25-generic #25-Ubuntu SMP Wed Mar 30 15:54:22 UTC 2022 x86_64
Build Date	Apr 7 2022 17:46:26
Build System	Linux

Virtual Directory Support	disabled
Configuration File (php.ini) Path	/etc/php/8.1/fpm
Loaded Configuration File	/etc/php/8.1/fpm/php.ini
Scan this dir for additional .ini files	/etc/php/8.1/fpm/conf.d
Additional .ini files parsed	/etc/php/8.1/fpm/conf.d/10-mysqlnd.ini, /etc/php/8.1/fpm/conf.d/10-opcache.ini, /etc/php/8.1/fpm/conf.d/10-pdo.ini, /etc/php/8.1/fpm/conf.d/15-xml.ini, /etc/php/8.1/fpm/conf.d/20-calendar.ini, /etc/php/8.1/fpm/conf.d/20-ctype.ini, /etc/php/8.1/fpm/conf.d/20-curl.ini, /etc/php/8.1/fpm/conf.d/20-dom.ini, /etc/php/8.1/fpm/conf.d/20-exif.ini, /etc/php/8.1/fpm/conf.d/20-ftp.ini, /etc/php/8.1/fpm/conf.d/20-gd.ini, /etc/php/8.1/fpm/conf.d/20-gettext.ini, /etc/php/8.1/fpm/conf.d/20-gmp.ini, /etc/php/8.1/fpm/conf.d/20-imap.ini, /etc/php/8.1/fpm/conf.d/20-ldap.ini, /etc/php/8.1/fpm/conf.d/20-mbstring.ini, /etc/php/8.1/fpm/conf.d/20-mysql.ini, /etc/php/8.1/fpm/conf.d/20-pdo_mysql.ini, /etc/php/8.1/fpm/conf.d/20-phar.ini, /etc/php/8.1/fpm/conf.d/20-posix.ini, /etc/php/8.1/fpm/conf.d/20-readline.ini, /etc/php/8.1/fpm/conf.d/20-shmop.ini, /etc/php/8.1/fpm/conf.d/20-simplexml.ini, /etc/php/8.1/fpm/conf.d/20-sockets.ini, /etc/php/8.1/fpm/conf.d/20-sysmsg.ini, /etc/php/8.1/fpm/conf.d/20-sysvsem.ini, /etc/php/8.1/fpm/conf.d/20-sysvshm.ini, /etc/php/8.1/fpm/conf.d/20-tokenizer.ini, /etc/php/8.1/fpm/conf.d/20-xmireader.ini, /etc/php/8.1/fpm/conf.d/20-xmlexer.ini, /etc/php/8.1/fpm/conf.d/20-xsl.ini
PHP API	20210902
PHP Extension	20210902

Step 7: Improve PHP Performance

The default PHP configurations (`/etc/php/8.1/fpm/php.ini`) are made for servers with very few resources (like a 256MB RAM server). To improve web application performance, you should change some of them.

We can edit the PHP config file (`php.ini`), but it's a good practice to create a custom PHP config file, so when you upgrade to a new version of PHP8.1, your custom configuration will be preserved.

```
sudo nano /etc/php/8.1/fpm/conf.d/60-custom.ini
```

In this file, add the following lines.

```
; Maximum amount of memory a script may consume. Default is 128M
memory_limit = 512M

; Maximum allowed size for uploaded files. Default is 2M.
upload_max_filesize = 20M

; Maximum size of POST data that PHP will accept. Default is 2M.
post_max_size = 20M

; The OPcache shared memory storage size. Default is 128
opcache.memory_consumption=256

; The amount of memory for interned strings in Mbytes. Default is 8.
opcache.interned_strings_buffer=32
```

```
linuxbabe@ubuntu: ~
GNU nano 6.2 /etc/php/8.1/fpm/conf.d/60-custom.ini
; Maximum amount of memory a script may consume. Default is 128M
memory_limit = 512M

; Maximum allowed size for uploaded files. Default is 2M.
upload_max_filesize = 20M

; Maximum size of POST data that PHP will accept. Default is 2M.
post_max_size = 20M

; The OPcache shared memory storage size. Default is 128
opcache.memory_consumption=256

; The amount of memory for interned strings in Mbytes. Default is 8.
opcache.interned_strings_buffer=32

^G Help      ^O Write Out ^W Where Is  ^K Cut       ^T Execute   ^G Location  ^M-U Undo
^X Exit      ^R Read File ^A Replace   ^U Paste     ^J Justify   ^_ Go To Line  ^H-E Redo
```

Save and close the file. Then reload PHP8.1-FPM for the changes to take effect.

```
sudo systemctl reload php8.1-fpm
```

OPcache improves the performance of PHP applications by caching precompiled bytecode. You can view OPcache stats via the `info.php` page. Below is a before and after comparison on one of my servers.

Before

Zend OPcache

Opcode Caching	Up and Running
Optimization	Enabled
SHM Cache	Enabled
File Cache	Disabled
Startup	OK
Shared memory model	mmap
Cache hits	717842
Cache misses	3145
Used memory	103145752
Free memory	27546000
Wasted memory	3525976
Interned Strings Used memory	6291000
Interned Strings Free memory	8
Cached scripts	3111
Cached keys	4374
Max keys	16229
OOM restarts	3
Hash keys restarts	0
Manual restarts	4

After

Zend OPcache

Opcode Caching	Up and Running
Optimization	Enabled
SHM Cache	Enabled
File Cache	Disabled
Startup	OK
Shared memory model	mmap
Cache hits	5660940
Cache misses	3524
Used memory	166117984
Free memory	370752928
Wasted memory	0
Interned Strings Used memory	9427840
Interned Strings Free memory	40903360
Cached scripts	3524
Cached keys	5141
Max keys	16229
OOM restarts	0
Hash keys restarts	0
Manual restarts	0

As you can see, before applying the custom PHP configuration, the RAM allocated to OPcache is almost used up. After applying the custom PHP configurations, OPcache is able to use more RAM for caching precompiled bytecode.

Congrats! You have successfully installed Nginx, MariaDB, and PHP8.1 on Ubuntu 22.04. For your server's security, you should delete `info.php` file now to prevent hackers from seeing it.

```
sudo rm /usr/share/nginx/html/info.php
```

Troubleshooting Tip

If you encounter errors, you can check the Nginx error log (`/var/log/nginx/error.log`) to find out what's wrong.

Nginx Automatic Restart

If for any reason your Nginx process is killed, you need to run the following command to restart it.

```
sudo systemctl restart nginx
```

Instead of manually typing this command, we can make Nginx automatically restart by editing the `nginx.service` systemd

service unit. To override the default systemd service configuration, we create a separate directory.

```
sudo mkdir -p /etc/systemd/system/nginx.service.d/
```

Then create a file under this directory.

```
sudo nano /etc/systemd/system/nginx.service.d/restart.conf
```

Add the following lines in the file, which will make Nginx automatically restart **5 seconds** after a failure is detected. The default value of `RestartSec` is **100ms**, which is too small. Nginx may complain that “start request repeated too quickly” if `RestartSec` is not big enough.

```
[Service]
Restart=always
RestartSec=5s
```

Save and close the file. Then reload systemd for the changes to take effect.

```
sudo systemctl daemon-reload
```

To check if this would work, kill Nginx with:

```
sudo pkill nginx
```

Then check Nginx status. You will find Nginx automatically restarted.

```
systemctl status nginx
```

MariaDB Automatic Start

By default, MariaDB is configured to automatically restart on-abort (/lib/systemd/system/mariadb.service).

However, if your server runs out of memory (oom) and MariaDB is killed by the oom killer, it won't automatically restart. We can configure it to restart no matter what happens.

Create a directory to store custom configurations.

```
sudo mkdir -p /etc/systemd/system/mariadb.service.d/
```

Create a custom config file.

```
sudo nano /etc/systemd/system/mariadb.service.d/restart.conf
```

Add the following lines in the file.

```
[Service]
Restart=always
RestartSec=5s
```

Save and close the file. Then reload systemd for the changes to take effect.

```
sudo systemctl daemon-reload
```

Next Steps

As always, if you found this post useful, then [subscribe to our free newsletter](#) to get more tips and tricks. You can also install

WordPress on top of the LEMP stack to create your own website or blog.
